Synthetic Turf Fiber Wear Test – Progress Report

Updated June 2016

Lisport wear testing was conducted at Penn State's Center for Sports Surface Research, University Park, PA. All samples were exposed to a total of 30,000 cycles on a Lisport wear tester.

Testing Methods

Fiber wear tests were conducted using a Lisport wear tester (pictured below). The Lisport wear tester consists of two cylinders outfitted with studs (cleats) that simulate field use. Different sprocket sizes on each cylinder allow for a sliding movement of one of the cylinders. The model used in this testing also included a sample tray that produced movement transverse to the linear movement of the cylinders, allowing for even wear across the entire sample. Each cycle is roughly equivalent to one hour of field use by users wearing cleated shoes. The method used is considered a modified version of both the European Standard for Surfaces for Outdoor Sports Areas - Exposure of Synthetic Turf to Simulated Wear (EN 15306) and the FIFA Quality Concept for Football Turf – Handbook of Test Methods (May, 2009 edition) as our machine includes plastic cleats with metal tips instead cleats made of 100% plastic. Each sample was filled with crumb rubber to a depth based on manufacturer specifications. Ten fibers were randomly removed after every 10,000 cycles for evaluation.

Fiber Evaluation

Each fiber was classified into one of four categories based on appearance:

Samples used in testing were obtained from athletic field managers and installers. If you would like to participate in our testing program, please visit our website for more details:

<http://plantscience.psu.edu/research/centers/ssrc/fibertest> . This report will be updated regularly as more samples are tested. Be sure to check back often for the most current results.
