# Phytotoxicity on an Annual Bluegrass Putting Green with Various Syngenta Fungicides 

T. Lulis, P. Rollo, C. Stephens, and J.E. Kaminski<br>Department of Plant Science<br>The Pennsylvania State University

## INTRODUCTION

An important factor in determining the suitability of fungicides used to control disease on golf course putting greens is the potential for phytotoxicity to desirable turfgrass species. For this reason, it is important to assess existing commercially available and experimental fungicides for their potential to injure turf. The objective of this research was to evaluate the injury potential of various Syngenta fungicides on an annual bluegrass putting green.

## MATERIALS \& METHODS

A one-year field study was initiated at the Valentine Turfgrass Research Center located in University Park, PA. Soil was a sandy loam with a pH of 7.1 and $2.6 \%$ organic matter. Annual bluegrass accounted for approximately $85 \%$ of the species within the study site when treatments were initiated on 8 Jul 2016, with creeping bentgrass (Agrostis stolonifera) accounting for the remaining $15 \%$. All fungicide treatments were applied with a $\mathrm{CO}_{2}$ pressurized ( 40 psi ) sprayer equipped with an airinduction flat fan nozzle (TeeJet Al9508EVS) and calibrated to deliver 2.0 gal of water $1000 \mathrm{ft}^{-2}$. The area was mowed five days per week to a height of 0.110 in. Preventive fungicide applications were applied on a 14-day interval prior to the initiation of the trial using boscalid ( 0.18 oz $1000 \mathrm{ft}^{-2}$ ) and tebuconazole ( 0.6 fl oz $1000 \mathrm{ft}^{-2}$ ). No additional fungicides were applied after treatment initiation. Treatments were initiated on 8 Jul 2016 and reapplied according to the application schedule. All treatments are listed in the data tables.

Plots measured $3 \mathrm{ft} \times 6 \mathrm{ft}$ and were arranged as a randomized complete block design with four replications. Injury was visually assessed on a 0 to 5 scale where $0=$ no phytotoxicity and $5=$ entire plot area injured by phytotoxicity. Turfgrass quality and

Figure 1. Phytotoxicity trial on a research putting green at the Joseph Valentine Turfgrass Research Center, 2016.
color were also visually assessed on a 1 to 9 scale where 1 = entire plot brown or dead and $9=$ optimum greenness and/or density. All data were subjected to analysis of variance and means were separated at $P \leq$ 0.05 according to Fisher's Protected least significant difference test.

## RESULTS \& DISCUSSION

Injury due to phytotoxicity was observed in several plots at various times during the duration of the trial. At no time during the trial was injury rated as unacceptable ( $\geq 3$ ) and there were no significant differences among treatments when rated for injury (Table 1). Quality and color were acceptable ( $\geq 6$ ) for all treatments on all rating dates and there were no significant differences among treatments on any rating date (Tables 1 and 2).

## ACKNOWLEDGEMENTS

We thank Syngenta, the Pennsylvania Turfgrass Council, and the Joseph Valentine Turfgrass Research Center staff for supporting this research.
